

# Lecture 7-1

Chap. 5 Network Layer, part II

# Chapter 4: Network Layer

- 4.1 Introduction
- 4.2 Virtual circuit and datagram networks
- 4.3 What's inside a router
- 4.4 IP: Internet Protocol
  - Datagram format
  - IPv4 addressing
  - ICMP
  - IPv6
- 4.5 Routing algorithms
  - Link state
  - Distance Vector
  - Hierarchical routing
- 4.6 Routing in the Internet
  - RIP
  - OSPF
  - BGP
- 4.7 Broadcast and multicast routing

# Interplay between routing, forwarding

# Graph abstraction

Graph:  $G = (N, E)$

$N$  = set of routers =  $\{ u, v, w, x, y, z \}$

$E$  = set of links =  $\{ (u,v), (u,x), (u,w), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) \}$

Remark: Graph abstraction is useful in other network contexts

Example: P2P, where  $N$  is set of peers and  $E$  is set of TCP connections

# Graph abstraction: costs

- $c(x,x') = \text{cost of link } (x,x')$ 
  - e.g.,  $c(w,z) = 5$
- cost could always be 1, or inversely related to bandwidth, or inversely related to congestion

Cost of path  $(x_1, x_2, x_3, \dots, x_p) = c(x_1, x_2) + c(x_2, x_3) + \dots + c(x_{p-1}, x_p)$

Question: What's the least-cost path between u and z ?

Routing algorithm: algorithm that finds least-cost path

# Routing Algorithm classification

## Global or decentralized information?

### Global:

- all routers have complete topology, link cost info
- “link state” algorithms

### Decentralized:

- router knows physically-connected neighbors, link costs to neighbors
- iterative process of computation, exchange of info with neighbors
- “distance vector” algorithms

## Static or dynamic?

### Static:

- routes change slowly over time

### Dynamic:

- routes change more quickly
  - periodic update
  - in response to link cost changes

# A Link-State Routing Algorithm

## Dijkstra's algorithm

- net topology, link costs known to all nodes
  - accomplished via "link state broadcast"
  - all nodes have same info
- computes least cost paths from one node ('source') to all other nodes
  - gives forwarding table for that node
- iterative: after  $k$  iterations, know least cost path to  $k$  dest.'s

## Notation:

- $c(x,y)$ : link cost from node  $x$  to  $y$ ;  
 $= \infty$  if not direct neighbors
- $D(v)$ : current value of cost of path from source to dest.  $v$
- $p(v)$ : predecessor node along path from source to  $v$
- $N'$ : set of nodes whose least cost path definitively known

# Dijkstra's Algorithm

1 **Initialization:**

2  $N' = \{u\}$

3 for all nodes  $v$

4 if  $v$  adjacent to  $u$

5 then  $D(v) = c(u,v)$

6 else  $D(v) = \infty$

7

8 **Loop**

9 find  $w$  not in  $N'$  such that  $D(w)$  is a minimum

10 add  $w$  to  $N'$

11 update  $D(v)$  for all  $v$  adjacent to  $w$  and not in  $N'$  :

12  $D(v) = \min( D(v), D(w) + c(w,v) )$

13 /\* new cost to  $v$  is either old cost to  $v$  or known

14 shortest path cost to  $w$  plus cost from  $w$  to  $v$  \*/

15 **until all nodes in  $N'$**

## Dijkstra's algorithm: example

Step	N'	D(v),p(v)	D(w),p(w)	D(x),p(x)	D(y),p(y)	D(z),p(z)
0	u	2,u	5,u	1,u	$\infty$	$\infty$
1	ux	2,u	4,x		2,x	$\infty$
2	uxy	2,u	3,y			4,y
3	uxyv		3,y			4,y
4	uxyvw					4,y
5	uxyvwz					

## Dijkstra's algorithm: example (2)

Resulting shortest-path tree from u:

Resulting forwarding table in u:

destination	link
v	(u,v)
x	(u,x)
y	(u,x)
w	(u,x)
z	(u,x)

# Dijkstra's algorithm, discussion

Algorithm complexity:  $n$  nodes

- each iteration: need to check all nodes,  $w$ , not in  $N$
- $n(n+1)/2$  comparisons:  $O(n^2)$
- more efficient implementations possible:  $O(n \log n)$

Oscillations possible:

- e.g., link cost = amount of carried traffic
